

In-Class Exercise Solutions: Halogen Isotope Patterns

- a. The isotopic abundance of Cl is 75% ^{35}Cl and 25% ^{37}Cl . Calculating the probability of an intermediate number of ^{35}Cl and ^{37}Cl atoms is complicated, but calculating the probability that all atoms will be one or the other is pretty simple: it's just P^z , where P is the probability of one atom being a particular type, and z is the number of atoms. So, for

number of Cl atoms (z)	probability of $(^{35}\text{Cl})_z$	probability of $(^{37}\text{Cl})_z$
1	$(0.75)^1 = 0.75$	$(0.25)^1 = 0.25$
2	$(0.75)^2 = 0.56$	$(0.25)^2 = 0.06$
3	$(0.75)^3 = 0.42$	$(0.25)^3 = 0.02$
4	$(0.75)^4 = 0.32$	$(0.25)^4 = 0.00$
5	$(0.75)^5 = 0.24$	$(0.25)^5 = 0.00$
6	$(0.75)^6 = 0.18$	$(0.25)^6 = 0.00$

Note that only the $z = 1$ row adds to 100%; the other rows have contributions from molecules with some ^{35}Cl and some ^{37}Cl atoms that aren't listed.

Looking at our $m/z = 354$ multiplet now, we can ask: what fraction of the total intensity is the lowest-mass ($m/z = 352$) peak? There are four significant peaks in the pattern, with intensities of $\sim 3:4:3:1$ maybe. That means that the lowest-mass peak isn't $1/3$ of the total intensity, but maybe $\sim 1/4$; that would point to the molecule having 5 Cl atoms. The rest of the molecule would then have mass $352 - 5(35) = 177$. That could make the molecular formula $\text{C}_{13}\text{H}_{21}\text{Cl}_5$, with an unsaturation number of 1; or $\text{C}_{14}\text{H}_9\text{Cl}_5$, with an unsaturation number of 8. If the molecule is aromatic (minimum UN = 4), the formula must be $\text{C}_{14}\text{H}_9\text{Cl}_5$.

MolE - Molecular Mass Calculator v2.02

Formula: $\text{C}_{14}\text{H}_9\text{Cl}_5$
 Monoisotopic mass : 351.91468
 [M+H]⁺ : 352.92196
 [M-H]⁻ : 350.90741

C (12.000) : 47.738 %
 H (1.007) : 2.577 %
 Cl (34.968) : 49.683 %

Clearly that is the hard way to do this kind of problem. The easier way would be to use a web-based calculator to show us the isotope pattern we should expect. For example, if I plug $\text{C}_{14}\text{H}_9\text{Cl}_5$ into the calculator at <http://library.med.utah.edu/masspec/mole.htm>, I get the output shown at right, which is awfully close to the spectrum above.

- b. I think each of the lower-mass multiplets match the % ^{35}Cl values we calculated in the chart in part (a). The pattern at 319 has three major peaks with intensities ~3:4:2; that would mean the first peak is about 33% of the total, and corresponds to a fragment with 4 Cl atoms. The pattern at 282 is a bit messy, but if we consider only the tallest peaks, the first tall peak could be 42% of the total, with 3 Cl atoms. And the "pattern" at 235 has a first peak with over half the total intensity for that group, suggesting a fragment with two Cl atoms.
